Atmospheric Neutrino Fluxes

- Historical introduction
- Sub-GeV v in three dimensions
- Multi-GeV and v-induced upward μ
- Atmospheric v as background & calibration for neutrino telescopes

Tom Gaisser August 20, 2004

Historical context

Detection of atmospheric neutrinos

- Markov (1960) suggests Cherenkov light in deep lake or ocean to detect atmospheric v interactions for neutrino physics
- Greisen (1960) suggests water Cherenkov detector in deep mine as a neutrino telescope for extraterrestrial neutrinos
- First recorded events in deep mines with electronic detectors, 1965: CWI detector (Reines et al.); KGF detector (Menon, Miyake et al.)

Two methods for calculating atmospheric neutrinos:

- From muons to parent pions infer neutrinos (Markov & Zheleznykh, 1961; Perkins)
- From primaries to π , K and μ to neutrinos (Cowsik, 1965 and most later calculations)
- Essential features known since 1961: Markov & Zheleznykh, Zatsepin & Kuz'min
- Monte Carlo calculations follow second method

Stability of matter: search for proton decay, 1980's v backg

- IMB & Kamioka -- water Cherenkov detectors
- KGF, NUSEX, Frejus, Soudan -- iron tracking calorimeters
- Principal background is interactions of atmospheric neutrinos
- Need to calculate flux of atmospheric neutrinos Tom Gaisser August 20, 2004 Atmospheric Neutrino Fluxes

Historical context (cont'd)

р

π

 ν_{μ}

ve

 v_{μ}

Atmospheric neutrino anomaly - 1986, 1988 ...

- IMB too few μ decays (from interactions of v_{μ}) 1986
- Kamioka μ-like / e-like ratio too small.
- Neutrino oscillations first explicitly suggested in 1988 Kamioka paper
- Hint of pathlength dependence from Kamioka, Fukuda et al., 1994

Discovery of atmospheric neutrino oscillations by S-K e

- Super-K: "Evidence for neutrino oscillations" at Neutriino 98
- Subsequent increasingly detailed analyses from Super-K 1998...
- Confirming evidence from MACRO and Soudan
- Analyses based on ratios comparing to 1D calculations

Need for precise, complete, accurate, 3D calculations

- $\Theta \sim P_T / E$ is large for sub-GeV neutrinos
- Bending of muons in geomagnetic field important for ν from μ decay
- Complicated angular/energy dependence of primaries (AMS measurement)
- Use improved primary spectrum and hadroproduction information

Tom Gaisser August 20, 2004

Atmospheric neutrino beam

- Up-down symmetric except for geomagnetic effects
- One detector for both
 - long baseline
 - short baseline
- $1 < L/E < 10^5 \text{ km/GeV}$
- $v_{\mu}/v_e \sim 2$ for $E_v < GeV$

Tom Gaisser August 20, 2004 Atmospheric Neutrino Fluxes

Overview of the calculation

Dy = primary flux & cutoffs & Yield

 $= \phi_p \otimes R_p \otimes \gamma_{p \to v_i} + \sum \{\phi_A \otimes R_A \otimes \gamma_{A \to v_i}\}$ $2 \text{ protons} \qquad 2 \text{ nuclei}$

Yield: $p \rightarrow \pi^{\pm} (k^{\pm}) \rightarrow \mu^{\pm} + V_{\mu} (\bar{V}_{\mu})$ $\downarrow \quad \bar{V}_{\mu} (V_{\mu}) + V_{e} (\bar{v}_{e}) + e^{\pm}$

[Signal ~ \$r. & Tr.]

Tom Gaisser August 20, 2004

Primary spectrum

- Largest source of overall uncertainty
 - 1995: experiments differ by 50% (see lines)
 - Present: AMS, BESS within 5% for protons
 - discrepancy for He larger,
 but He only 20% of
 nucleon flux
 - CAPRICE lower by 15-20%

Primary spectrum: new standard?

Tom Gaisser August 20, 2004

Primary spectrum

- Compare 3 fits using same ۲ event generator (Target 2.1)
 - AGLS = PRD 53: 1996
 - Hamburg = TG et al., ICRC 2001 p. 1643 used for comparisons
 - 1.7 x E^{-2.7} (c.g.s.) for analytic estimates

0.6

Ratio

Hadronic interactions

- Sub-GeV v depend most on treatment of π production
- K⁺ dominate $E_v > 100 \text{ GeV}$
- Compare 5 calculations:
 - Bartol (Target-1, 2.1)
 - Honda et al. (1995: Fritiof; present: Dpmjet3)
 - Battistoni et al. (Fluka)
- Uncertainties from interactions ~ +/-15%

Tom Gaisser August 20, 2004

Hadronic interactions

Example: Compare original Target 1 with Target 2.1 (Target 3D): pions down, kaons up

Tom Gaisser August 20, 2004

Comparison (using same flux)

- New calculations lower than old, e.g.:
 - Target-2.1/ -1
 - Dpmjet3 / HKKM
 - 3 new calculations agree at Kamioka but less well at Soudan/SNO
- Larger uncertainty at high geomagnetic λ

 Interactions < 10 GeV are important

Tom Gaisser August 20, 2004 Atmospheric Neutrino 1

Super-K atmospheric neutrino data (T. Kajita)

Flavor ratio at production

- $r = v_{\mu}/v_{e}$ at production sets background for search for effects of solar and s₁₃ mixing
- $\Delta_{e} = P_{2}(r \cos^{2}\theta_{23} 1)$ Peres & Smirnov, 2004
- $\rightarrow 0$ for r = 2, $\theta_{23} = 45^{\circ}$
- $r_{sub-GeV} \sim 2.04 2.1$

Tom Gaisser August 20, 2004

New hadro-production data expected

- Diagram:
 - Lego plot shows phase space weighting for sub-GeV events
 - Bars show existing data
- New sources of data
 - HARP
 - NA49 (P322)
 - MIPP (E907)

Tom Gaisser August 20, 2004

3-dimensional effects

- Characteristic 3D feature:
 - excess of v near horizon
 - shown in top, left panel
 - lower panels show directions of μ and e
 - cannot see 3D effect directly; however:
- Horizontal excess is associated with a change in path-length distribution

From Battistoni et al., Astropart. Phys. 12 (2000) 315

Path-length dependence

- Path length shorter near horizon on average in 3D case
 - $-\cos(\theta) > 0$ only,
 - phase space favors nearby interaction scattering to large angle
 - 5-10% (E_v ~0.3-1 GeV)
- Size of effect not yet known
 - δm²L/E: decrease L by 5% in 1 angular bin out of 20
 - increase δm^2 by ~1%?

Difference between 3D and 1D calculations

 $\cos \theta_{z}$

Geomagnetic cutoffs & E-W effect as a consistency check

- Picture shows:
 - 20 GeV protons in geomagnetic equatorial plane
 - arrive from West and from near the vertical
 - but not from East
- Comparison to data:
 - provides consistency test of data & analysis

From cover of "Cosmic Rays" by A.M. Hillas (1972) Atmospheric Neutrino Fluxes

Tom Gaisser August 20, 2004 Cutoffs at Super-K Measurement of East-West effect with atmospheric neutrinos--an important confirmation of analysis & interpretation of Super-K data as neutrino oscillations

 $v \text{ flux}, 0.4 < E_v < 3 \text{ GeV}$

 $-0.5 < \cos(\theta) < 0.5$

Tom Gaisser August 20, 2004

Higher energy atmospheric v

- Mean $E_{\nu} \sim 100$ GeV for ν induced upward μ
- Note difference in normalization

Tom Gaisser August 20, 2004

Analytic approximation

 $\phi_{v}(E_{v}) = \frac{\phi_{v}(E_{v})}{1-\overline{2}_{NN}} \underbrace{\frac{\overline{2}_{N\pi} \overline{2}_{\pi v}}{1+D_{\pi} \underbrace{\cos \varphi } E_{v}}}_{E_{\pi}}$

$$\mathbf{v} = \mathbf{v}_{\mu} + \overline{\mathbf{v}}_{\mu}$$

-- good for $E_v > 10 \text{ GeV}$

 $Z_{\pi\nu} = .087$ $Z_{\mu\nu} = .34$ $E_{\pi} = 115 \ GeV$ $E_{\mu} = 850 \ GeV$

Tom Gaisser August 20, 2004

High energy (e.g. $\nu_{\mu} \rightarrow \mu$)

- Importance of kaons
 - main source of v> 100 GeV
 - $p \rightarrow K^+ + \Lambda$
important
 - Charmed analog important for prompt leptons

Atmospheric Neutrino Fluxes

Tom Gaisser August 20, 2004

Importance of kaon production

Tom Gaisser August 20, 2004

Calibration with atmospheric v

- MINOS, etc.
- Neutrino telescopes
- Example^{***} of v_{μ} / v_{e}
 - flavor ratio
 - angular dependence

***Note: this is maximal effect: horizontal = 85 - 90 deg in plots

Tom Gaisser August 20, 2004

Global view of atmospheric v spectrum

Summary - oscillations

- Evidence for v oscillation uses ratios:
 - Contained events
 - $(v_{\epsilon} / v_{\mu})_{data} / (v_{e} / v_{\mu})_{calculated}$
 - upward / downward
 - Neutrino-induced upward muons
 - stopping / through-going
 - vertical / horizontal
 - Broad response functions minimize dependence on slope of primary spectrum
- Uncertainties tend to cancel in comparison of ratios
- Observation of geomagnetic effects confirms experiment & interpretation

Tom Gaisser August 20, 2004

Summary & outlook

- Current generation of calculations is 3D but
 - changes due to improved treatment of primary flux and treatment of hadronic interactions, not primarily to 3D
 - Need further refinements to see sub-dominant aspects of three flavor oscillations in atmospheric neutrinos
 - Calculate $20 < E_v < 100$ MeV: background for SNR neutrinos. Only FLUKA has done this so far
- Incorporate new hadro-production results
 - HARP below 15 GeV
 - NA 49, MIPP ~ 100 GeV
- Uncertainty in kaon production limits accuracy of flux above 100 GeV
- Uncertainty in charm production (prompt v) limits sensitivity for diffuse astrophysical (> TeV) neutrinos

Tom Gaisser August 20, 2004
